

# Quad SPI to 8 rows

## Pros

- low I/O
- unlimited data
- simple

## Cons

- mux
- latency
- 2-way comm.

# Direct mux to rows

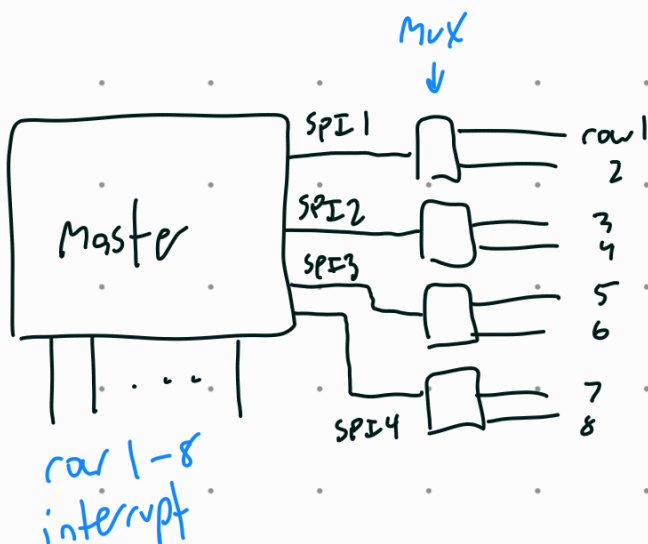

## Pros

- no comm. protocol
- very simple

## Cons

- lots of mux
- still latency

# Individual interrupt + SPI

explanation: same as first, but use interrupt from rows to know when to grab data instead of polling

pro: less latency

## Decided method: multiplexed SPI

### Pros

- design allows for virtually unlimited data to be sent between UC, allowing us to change data in future
- allows for unlimited expansion since we can simply use encoder/decoders to address lots of rows
- simple implementation

### Cons

- requires multiplexing
- need to poll each row to get all data (can be mitigated with small data size)

## Required testing:

- multiplex SPI lines
- test communication speed (22.5 Mbps advertised)

Ensure data reliability at high speed
